Suppression of disturbances
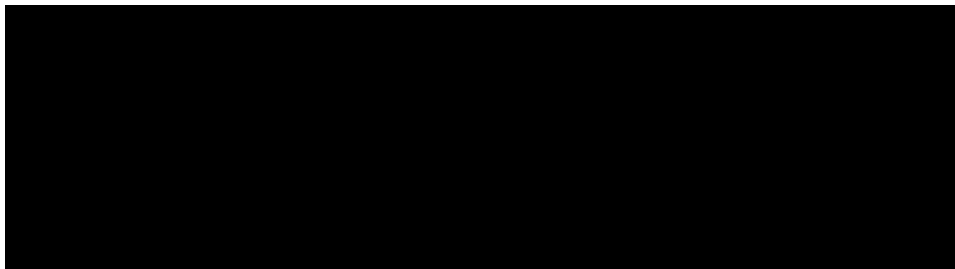

The weight is

$$W_S(s) = \ldots$$

Figure 1: Simulation results with system G, using W_S.

How much is the disturbance damped on the output? What amplification is required for a P-controller to get the same performance, and what are the disadvantages of such a controller?

....

....

Robustness

What is the condition on T to guarantee stability according to the small gain theorem, and how can it be used to choose the weight W_T?

....

....

The weights are

$$W_S(s) = \dots$$
$$W_T(s) = \dots$$

Is the small gain theorem fulfilled?

....

..

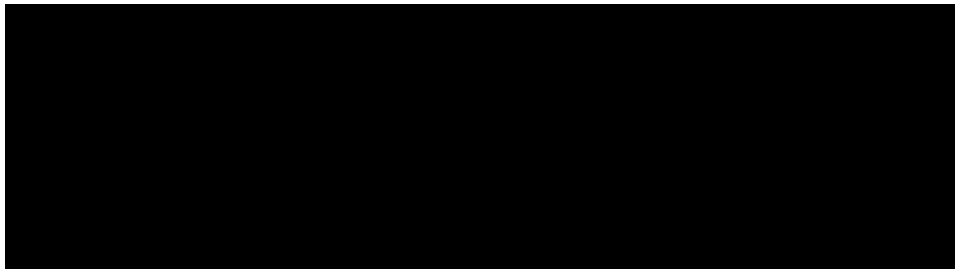

Figure 2: Bode diagram showing that the small gain theorem is satisfied.

Figure 3: Simulation results with system G_0, using W_S and W_T.

Compare the results to the previous simulation

....

....

Control signal

The weights are

$$W_S(s) = \dots$$
$$W_T(s) = \dots$$
$$W_U(s) = \dots$$

Compare the results to the previous simulations

....

....

Figure 4: Simulation results with system G_0, using W_S, W_T and W_U.
